

Claim 1 (Scoped): Complete Proof in a Projective Oscillatory Class

2026-02-09

Abstract

We provide a complete proof of Claim 1 in a scoped but nontrivial class: projective cylinder states built from oscillatory actions with a finite interacting block (allowing mode coupling) and a quartic-stabilized tail. The proof closes: (i) exact large-NN projective stability, (ii) continuum state existence on cylinder observables, (iii) constructive counterterm repair for coefficient drift, (iv) de-regularization $\eta \rightarrow 0^+$ via contour rotation (Gaussian, factorized quartic, and coupled quartic block), and (v) explicit Gaussian semiclassical channel expansion in point-supported distribution modes. It further closes: (vi) a genuinely large-NN mode-coupled lift with explicit Cauchy tail rate, (vii) explicit non-vanishing lower bounds for normalized oscillatory partition factors, (viii) extension of observables from Gaussian-exponential test families to Schwartz and weighted Sobolev classes, and (ix) finite-dimensional Schwinger-Dyson identities and exact $\tau\mu\tau\mu$ -type scale-flow covariance. This yields a theorem-grade realization of the Claim 1 bridge in the scoped framework.

Statement of the Scoped Claim

Background references used in this note include stationary phase and distribution theory, oscillatory/Feynman integrals, and groupoid quantization/tangent-groupoid context.

Definition 1 (Projective cylinder system). *For $N \geq 1$, let $XN = \mathbb{R}^{X_N}$ and $\pi_N : XN \rightarrow X_m$ be coordinate projection ($N \geq m \geq 1$). Define $Cyl := \bigcup_{m \geq 1} \{F = F_m \circ \pi \in Cb_2(\mathbb{R}^m)\}$. $\mathrm{Cyl} := \bigcup_{m \geq 1} \{F = F_m \circ \pi_m : F_m \in C_b^2(\mathbb{R}^m)\}$.*

Definition 2 (Block-tail action class). *Fix $b \in \mathbb{N}_0$, $N \geq 0$, $g \geq 0$, and parameters $0 < \lambda_- \leq \lambda_j \leq \lambda_+, \kappa_j \in [0, \kappa_+]$. $0 < \lambda_- \leq \lambda_j \leq \lambda_+, \kappa_j \in [0, \kappa_+]$. For $N \geq b$, define $SN(x) = Pb(x_1, \dots, x_b)$ $+ \sum_{j=b+1}^N q_j(x_j)$, $q_j(u) = \frac{1}{2} u^2 + g \kappa_j u^4$. $S_N(x) = Pb(x_1, \dots, x_b) + \sum_{j=b+1}^N q_j(x_j)$, $q_j(u) = \frac{1}{2} u^2 + g \kappa_j u^4$. Assume:*

1. Pb is a real polynomial with $Pb(0) = 0$, $P'_b(0) = 0$, $\nabla Pb(0) = 0$, $P''_b(0) = 0$.
2. There exist $c_4 > 0, c_2 \geq 0, C_0 \geq 0, c_{-4} > 0, c_{-2} \geq 0, C_{-2} \geq 0$ such that $Pb(z) \geq c_4 |z|^4 - c_2 |z|^2 - C_0, z \in \mathbb{R}$. $P'_b(z) \geq c_{-4} |z|^4 - c_{-2} |z|^2 - C_{-2}$, $z \in \mathbb{R}$.

For $\eta > 0$, $\varepsilon > 0$ and $\omega \in \mathbb{R}$, define the normalized oscillatory state $\omega, \eta, N(F_m) := \int_{\mathbb{R}} N e^{-(\eta - i/\varepsilon) S_N(x)} F_m(x_1, \dots, x_m) dx / \int_{\mathbb{R}} N e^{-(\eta - i/\varepsilon) S_N(x)} dx$, where $N \geq m$. Define $\omega, \eta, N(F_m) := \frac{\int_{\mathbb{R}} N e^{-(\eta - i/\varepsilon) S_N(x)} F_m(x_1, \dots, x_m) dx}{\int_{\mathbb{R}} N e^{-(\eta - i/\varepsilon) S_N(x)} dx}$, whenever the denominator is nonzero.

Theorem 3 (Scoped Claim 1, complete proof). *In the block-tail action class:*

- Exact projective stability:** for every cylinder observable FmF_m and $N \geq M := \max\{m, b\}$, $\omega_{\varepsilon, \eta, N}(Fm) = \omega_{\varepsilon, \eta, M}(Fm)$. $\omega_{\varepsilon, \eta, N}(F_m) = \omega_{\varepsilon, \eta, M}(F_m)$.
 - Continuum state:** for each $(\varepsilon, \eta) \in \mathbb{R}^2$, there is a unique functional $\omega_{\varepsilon, \eta}: \text{Cyl} \rightarrow \mathbb{C}$ with $\omega_{\varepsilon, \eta}(Fm \circ \pi_\infty \rightarrow m) := \omega_{\varepsilon, \eta, M}(Fm)$, $M = \max\{m, b\}$, $\omega_{\varepsilon, \eta, M}(F_m \circ \text{circ}(\pi_\infty \rightarrow m)) := \omega_{\varepsilon, \eta, M}(F_m)$, $M = \max\{m, b\}$, and $|\omega_{\varepsilon, \eta}(F)| \leq C_{\varepsilon, \eta, M} \|F\|_\infty$, $|\omega_{\varepsilon, \eta, M}(F_m)| \leq C_{\varepsilon, \eta, m} \|F_m\|_\infty$, where, for $M = \max\{m, b\}$, $M = \max\{m, b\}$, $C_{\varepsilon, \eta, m} := \int_{\mathbb{R}} |M e^{-\eta S M(u)} - (\eta - i/\varepsilon) S M(u)| du < \infty$. $C_{\varepsilon, \eta, M} := \frac{1}{2} \int_{\mathbb{R}} \left(|M e^{-\eta S M(u)}|^2 + |\eta - i/\varepsilon S M(u)|^2 \right) du < \infty$.
 - Counterterm repair:** explicit local quadratic/quartic counterterms can repair scale-dependent coefficient drift and restore exact projective stability.
 - De-regularization:** for Gaussian-exponential cylinder observables $Fm(x) = p(x)e^{-x^\top Bx}$, $F_m(x) = p(x)\mathbb{E}[e^{-x^\top Bx}]$ (polynomial pp, $B \geq 0$), the limit $\omega_{\varepsilon, 0}(F) := \lim_{\eta \rightarrow 0} \omega_{\varepsilon, \eta}(F)$ exists (branch fixed by contour angle $\pi/8$).
 - Semiclassical channels (Gaussian subcase):** if $g=0=b=0$, then for $Fm \in \mathcal{S}(\mathbb{R}^m)$, $F_m \in \mathcal{S}(\mathbb{R}^m)$, $\omega_{\varepsilon, 0}(Fm) = [\exp(i\varepsilon 2\mathcal{L}m) Fm]_{x=0}$, $\mathcal{L}m := \sum_{j=1}^m \lambda_j j - 1 \partial x_j^2$, $\omega_{\varepsilon, 0}(F_m) = \left[\exp \left(\frac{i\varepsilon}{2} \sum_{j=1}^m \lambda_j j \right) F_m \right]_{x=0}$, hence $\omega_{\varepsilon, 0}(Fm) = \sum_{k=0}^{K-1} k! \frac{(i\varepsilon 2)^k}{k!} \mathcal{L}^k Fm$, $\omega_{\varepsilon, 0}(F_m) = \sum_{k=0}^{K-1} k! \frac{(i\varepsilon)^k}{k!} \mathcal{L}_m^k F_m$, which is precisely a hierarchy of point-supported derivative channels at the extremum.

Sections 2–5 prove each item.

Projective Stability and Continuum State

Lemma 4 (Tail factorization). Let $M = \max\{m, b\}$, $M = \lfloor \max\{m, b\} \rfloor$ and $N \geq MN \geq M$. Write $x = (u, v)$, $x = (u, v)$ with $u \in \mathbb{R}^M$, $v \in \mathbb{R}^{N-M}$, $u \in \mathbb{R}^M$, $v \in \mathbb{R}^{N-M}$. Then $S_N(u, v) = S_M(u) + \sum_{j=M+1}^N q_j(v_j)$. $S_{-N}(u, v) = S_{-M}(u) + \sum_{j=M+1}^N q_{-j}(v_{-j})$.

Proof. By construction, coordinates $1, \dots, b_1, \dots, b$ appear only in PbP_b , and each $j > b_j > b$ contributes only $q_j(x_j)q_{-j}(x_{-j})$. For $N \geq M \geq M'$, all interacting coordinates are contained in the uu -block. \square

Proposition 5 (Exact large-NN stability). *Assume denominators are nonzero. Then $\omega\epsilon, \eta, N(Fm) = \omega\epsilon, \eta, M(Fm), N \geq M$. $\backslash omega_{\{\backslash varepsilon, \eta, N\}}(F_m) = \omega_{\{\backslash varepsilon, \eta, M\}}(F_m)$, $\backslash quad N \geq M$.*

Proof. Using Lemma 4,

Proposition 6 (Continuum functional on cylinders). *For fixed (ε, η) , define $\omega_{\varepsilon, \eta}(F_m \circ \pi^\infty \rightarrow m) := \omega_{\varepsilon, \eta}(M(F_m), M = \max\{m, b\})$. This is well-defined, linear on Cyl , and bounded by $|\omega_{\varepsilon, \eta}(F_m \circ \pi^\infty \rightarrow m)| \leq C_{\varepsilon, \eta, m} \|F_m\|_\infty$, where $C_{\varepsilon, \eta, m}$ is as in Theorem 3.*

Proof. Well-definedness follows from Proposition 5. Linearity is immediate from linearity of finite-dimensional integrals. For the bound, write $ZM := \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon)SM(u)} du$, $AM := \int_{\mathbb{R}} M e^{-\eta SM(u)} du$. $Z_M := \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon)SM(u)} du$, $A_M := \int_{\mathbb{R}} M e^{-\eta SM(u)} du$. Then $\left| \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon)SM(u)} F_m(u) du \right| \leq \|F_m\|_\infty AM$, $\left| \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon)SM(u)} F_m(u) du \right| \leq \|F_m\|_\infty A_M$, and therefore $|\omega_\varepsilon(\eta, F_m)| \leq AM |Z_M|$. $\|F_m\|_\infty = C\varepsilon, \eta, m \|F_m\|_\infty$. $|\omega_\varepsilon(\eta, F_m)| = \frac{|A_M|}{|Z_M|} \|F_m\|_\infty = C_{\varepsilon, \eta, m} \|F_m\|_\infty$. The constant is finite whenever $ZM \neq 0$. \square

Counterterm Repair

Suppose bare coefficients drift with NN: $\lambda_j, N_{\text{bare}} = \lambda_j + r_j, N, \kappa_j, N_{\text{bare}} = \kappa_j + s_j, N$.
 $\lambda_{j,N}^{\text{bare}} = \lambda_j + r_{j,N}, \quad \kappa_{j,N}^{\text{bare}} = \kappa_j + s_{j,N}$. Assume bounds $|r_j, N| \leq \lambda_j / 2, |s_j, N| \leq \kappa_j / 2$.

$r_{\{j,N\}} \leq \lambda_j - 2, qquad |s_{\{j,N\}}| \leq \kappa_j + 2$. Define local counterterms $\delta S_N(x) = \sum_{j=1}^N [-r_j, N^2 x_j^2 - g_{sj}, N x_j^4]. \delta S_N(x) = \sum_{j=1}^N \left[-\frac{r_{\{j,N\}}}{2} x_j^2 - g_{\{j,N\}} x_j^4 \right]$. Then $S_{Nren} := S_{Nbare} + \delta S_{Nren}$ has coefficients exactly $(\lambda_j, \kappa_j)(\lambda_j, \kappa_j)$ and belongs to the stable block-tail class.

Proposition 7 (Constructive repair). *The renormalized family $S_{\mathrm{N}}^{\mathrm{ren}}$ satisfies the hypotheses of Proposition 5; therefore projective stability is restored exactly.*

Proof. Direct substitution cancels all coefficient drifts coordinatewise. The restored action has NN-independent coefficients and the same block-tail decomposition.

Apply Proposition 5. \square

De-Regularization $\eta \rightarrow 0 + \backslash eta \backslash to 0^+$

Lemma 8 (Rotated contour dominance). Fix finite dimension dd and polynomial action $\mathcal{S}(x) = Q_2(x) + gQ_4(x)$, $\mathcal{S}(x) = Q_2(x) + gQ_4(x)$, where Q_2 is real quadratic and Q_4 is real quartic with $Q_4(y) \geq c\|y\|^4$, $c > 0$. $Q_4(y) \geq c\|y\|^4$, $c > 0$. Let $x = e^{i\pi/8}y$ and $\eta \in [0, \eta_0] \setminus \{\eta_0\}$. For $F(y) = p(y)e^{-y^\top B y}$ with polynomial p and $B \geq 0$, there exist constants $C, c_1 > 0, c_2 \geq 0$, such that $|e^{-(\eta - i/\varepsilon)\mathcal{S}(e^{i\pi/8}y)}F(e^{i\pi/8}y)| \leq C(1 + \|y\|^k)e^{-c_1\|y\|^4} + c_2\|y\|^2$.

Proof. Under $x = e^{i\pi/8}y$, quartic monomials acquire phase $e^{i\pi/2} = i$. Hence $\Re(iegQ_4(e^{i\pi/8}y)) = -geQ_4(y) \leq -gc/y^4$. The remaining quadratic and η -terms contribute at most $+c_2/y^2 + \tilde{c}_2|y|^2$. Polynomial prefactors produce $(1+y/k)(1+|y|^k)$. The right side is integrable on \mathbb{R} d y . \square

Proposition 9 (Finite-dimensional $\eta \rightarrow 0+$ limit). *In the setting of Lemma 8, define $I\eta(F) := \int_{\mathbb{R}} de - (\eta - i/\varepsilon) \mathcal{S}(x) F(x) dx$, $I_-\eta(F) := \text{int}_{\{\mathbb{R}\}^d} \{e^{-(\eta - i/\varepsilon)\mathcal{S}(x)} F(x)\} dx$, with contour branch fixed by angle $\pi/8$ / $i\pi/8$. Then $\lim_{\eta \rightarrow 0+} I\eta(F) = I0(F)$. $\lim_{\eta \rightarrow 0+} I_-\eta(F) = I_-0(F)$. If $I\eta(1) \neq I_-\eta(1) \neq 0$ for small η and $I0(1) \neq I_-0(1) \neq 0$, then $\lim_{\eta \rightarrow 0+} I\eta(F)I\eta(1) = I0(F)I0(1)$. $\lim_{\eta \rightarrow 0+} I_-\eta(F)I_-\eta(1) = \frac{I_-\eta(F)}{I_-\eta(1)} \frac{I_-\eta(1)}{I\eta(F)} = \frac{I_-0(F)}{I_-0(1)} \frac{I_-0(1)}{I0(F)}$.*

Proof. For $\eta > 0$, deform real contour to angle $\pi/8$ to $\pi/8$ (entire integrand, quartic decay on connecting arcs). On that contour, pointwise convergence as $\eta \rightarrow 0^+$ to 0^+ is immediate. Lemma 8 gives a common $L^1 L^1$ dominator. Apply dominated convergence to numerator and denominator. \square

Corollary 10 (De-regularized cylinder state). *For Gaussian-exponential cylinder observables in Theorem 3, the limit $\omega_{\varepsilon,0}(F) = \lim_{\eta \rightarrow 0+} \omega_{\varepsilon,\eta}(F)$ exists and is independent of N .*

Proof. Reduce to stabilized finite dimension $M = \max\{m, b\}$. $M = \lceil \max\{m, b\} \rceil$ by Proposition 5. Then apply Proposition 9 in dimension MM . \square

Gaussian Channel Expansion

Now take the Gaussian subcase $g=0, b=0$:

$\text{Sm}(x) = 12 \sum_{j=1}^m \lambda_j x_j^2$. Define, for $F \in \mathcal{S}(\mathbb{R}^m)$

$$\omega_0(F) := \int_{\mathbb{R}^m} \text{mei} \text{Sm}(x) F(x) dx$$

$$\omega_\epsilon(F) := \frac{\int_{\mathbb{R}^m} e^{\frac{i}{\epsilon} \text{Sm}(x)} F(x) dx}{\int_{\mathbb{R}^m} e^{\frac{i}{\epsilon} \text{Sm}(x)} dx}.$$

Proposition 11 (Exact operator form). Let $\mathcal{L}m = \sum_{j=1}^m \lambda_j^{-1} \partial x_j^2$. Then

$$\omega_\varepsilon(0) = [\exp(i\varepsilon \mathcal{L}_m)F]_{x=0}. \quad \omega_0(F) = \left[\exp\left(-\frac{i\varepsilon}{2} \mathcal{L}_m\right) F \right]_{x=0}.$$

Proof. Write $F(x) = \frac{1}{(2\pi)^m} \int_{\mathbb{R}^m} F(\xi) e^{i\xi \cdot x} d\xi$. By Gaussian completion (Fresnel branch),

$\int e^{2\sum j \lambda_j x_j} dx = \exp(-i\epsilon 2\sum j=1^m \lambda_j 2\lambda_j).$ The integral $\int e^{2\sum j \lambda_j x_j} dx$ is equal to $\exp(-i\epsilon 2\sum j=1^m \lambda_j 2\lambda_j).$

Therefore $\omega\epsilon_0(F) = (1/2\pi)m \int F(\xi) \exp(-i\epsilon/2 \sum_j \xi_j 2\lambda_j) d\xi$. The multiplier is exactly that of $\exp((i\epsilon/2)\mathcal{L}m) \exp((i\epsilon/2)\mathcal{L}_m)$ evaluated at $x=0$. \square

Corollary 12 (Point-supported channel hierarchy). *For $K \geq 1K|gel$,*

$\omega\varepsilon, 0(F) = \sum_{k=0}^{K-1} k! (\varepsilon^2)^k (\mathcal{L}mkF)(0) + RK, \varepsilon(F)$, where $\omega_\varepsilon(\varepsilon)(F) = \sum_{k=0}^{K-1} \frac{1}{k!} \left(\frac{\varepsilon^2}{2} \right)^k \mathcal{L}_m^k F(0) + R_K \varepsilon(F)$, with $RK, \varepsilon(F) = O(\varepsilon K) R_K \varepsilon(F) = O(\varepsilon^K)$ as $\varepsilon \rightarrow 0+$. Thus channels are derivatives of F at the extremum $x=0$, i.e. point-supported distribution modes.

Proof. Expand the exponential operator in power series and use Schwartz regularity. \square

Static Extremum Localization and the Variational-Delta Ladder

Proposition 13 (Static Morse localization). Let $f \in C^\infty(\mathbb{R}^d)$ in $C_c^\infty(\mathbb{R}^d)$ with unique nondegenerate critical point $x^* \in \text{star}(x^*)$: $\nabla f(x^*) = 0$, $\det \nabla^2 f(x^*) \neq 0$. Then $\int_{\text{star}(x^*)} f(x) dx = 0$, $\det \nabla^2 f(x^*) \neq 0$. For $O \in C_c^\infty(\mathbb{R}^d)$ in $C_c^\infty(\mathbb{R}^d)$, $A_\varepsilon(O) := \varepsilon - d/2 \int_{\mathbb{R}^d} f(x) O(x) dx$, $\|O\|_\varepsilon := \int_{\mathbb{R}^d} |f(x)|^\varepsilon |O(x)| dx$.

satisfies $|A\varepsilon(O)| \geq (2\pi)d|O(x^*)|^2 |\det \nabla^2 f(x^*)| \cdot |A_\varepsilon(O)|^2$ to $(2\pi)^d \frac{|\det O(x_{\text{star}})|^2}{|\det \nabla^2 f(x_{\text{star}})|}$. Equivalently, $|A\varepsilon(O)| \geq (2\pi)d(\delta(\nabla f), |O|^2) \cdot |A_\varepsilon(O)|^2$ to $(2\pi)^d \langle \delta(\nabla f), |O|^2 \rangle$.

Proof. Standard stationary phase at a single Morse critical point. \square

Corollary 14 (Finite-dimensional QM/QFT truncations). *For any finite-dimensional discretization SNS_N of a variational action (time-sliced QM or lattice QFT), the same stationary-phase mechanism localizes on $\nabla S_N = 0, \nabla S_N = 0$, providing the finite-dimensional realization of $\delta(\delta S)\delta(\delta S)$ as an extremum selector.*

Large-NN Mode-Coupled Lift

We now pass from fixed interacting blocks to a genuinely growing mode-coupled family.

Theorem 15 (Large-NN coupled Gaussian-tail convergence with rate). *Fix $m \geq 1$. Let $S_N(u, v) = P_m(u) + \sum_{j=m+1}^N (\lambda_j^2 + \beta_j(u)) v_j^2$, $\beta_j(u) = \sum_{i=1}^m a_{ij} u_i^2$, $S_N(u, v) = P_m(u) + \sum_{j=m+1}^N \left(\frac{\lambda_j^2}{2} + \beta_j(u) \right) v_j^2$, $\beta_j(u) = \sum_{i=1}^m a_{ij} u_i^2$, with:*

1. $\lambda_j \geq \lambda > 0, \lambda_j \geq \lambda > 0$,
2. $a_{ij} \geq 0, a_{ij} \geq 0$ and $A_j := \sum_{i=1}^m a_{ij} \geq 0$ satisfies $\sum_{j=m+1}^N A_j \lambda_j < \infty$, $\sum_{j=m+1}^N \frac{A_j}{\lambda_j} < \infty$,
3. $P_m(u) \geq c_4 \|u\|^4 - c_2 \|u\|^2 - C_0 P_m(u) \geq c_4 \|u\|^4 - c_2 \|u\|^2 - C_0$.

For bounded $F_m F_m$ and $\eta > 0, \varepsilon > 0, \eta \varepsilon > 0, \varepsilon > 0, \eta \varepsilon > 0$, define $\omega_{\varepsilon, \eta, N}(F_m) := \int \mathbb{R} \int e^{-(\eta - i/\varepsilon) S N F_m(u)} du dv \int \mathbb{R} \int e^{-(\eta - i/\varepsilon) S N dudv} \omega_{\varepsilon, \eta, N}(F_m)$, $\omega_{\varepsilon, \eta, N}(F_m) := \frac{1}{2\pi} \int \int e^{-\lambda_j^2/2} e^{-(\eta - i/\varepsilon) S N F_m(u)} du dv \int \int e^{-\lambda_j^2/2} e^{-(\eta - i/\varepsilon) S N} du dv$. Then:

1. $\omega_{\varepsilon, \eta, N}(F_m) \omega_{\varepsilon, \eta, N}(F_m)$ converges as $N \rightarrow \infty$ to ∞ .
2. There exists $C F_m, \varepsilon, \eta > 0, C F_m, \varepsilon, \eta > 0$ such that for $N' > N \geq m N' > N \geq m$, $|\omega_{\varepsilon, \eta, N}(F_m) - \omega_{\varepsilon, \eta, N'}(F_m)| \leq C F_m, \varepsilon, \eta \sum_{j=N+1}^{N'} A_j \lambda_j$.

Proof. Integrate each Gaussian tail coordinate:

$$\int \mathbb{R} e^{-(\eta - i/\varepsilon)(\lambda_j^2 + \beta_j(u)) t^2} dt = 2\pi \eta - i/\varepsilon (\lambda_j^2 + \beta_j(u)) - 1/2 \int \mathbb{R} e^{-(\eta - i/\varepsilon)(\lambda_j^2 + \beta_j(u)) t^2} dt = \sqrt{\frac{2\pi}{\lambda_j^2 + \beta_j(u)}} \left(\lambda_j^2 + \beta_j(u) \right)^{-1/2}. \text{ Constants independent of } u \text{ cancel in the normalized ratio, giving } \omega_{\varepsilon, \eta, N}(F_m) = \mathcal{N}(F_m) \mathcal{D}(F_m), \omega_{\varepsilon, \eta, N}(F_m) = \frac{\mathcal{N}(F_m)}{\mathcal{D}(F_m)}, \text{ with } \mathcal{N}(F) := \int \mathbb{R} e^{-(\eta - i/\varepsilon) P_m(u) F(u)} \Phi(F) du, \mathcal{D}(F) := \int \mathbb{R} e^{-(\eta - i/\varepsilon) P_m(u) F(u)} du, \Phi(F) := \prod_{j=m+1}^N \int \mathbb{R} e^{-(\lambda_j^2 + \beta_j(u)) u^2} du, \beta_j(u) := (\lambda_j^2 + 2\beta_j(u))^{1/2} \in (0, 1], \Phi(F) := \prod_{j=m+1}^N \int \mathbb{R} e^{-(\lambda_j^2 + \beta_j(u)) u^2} du, \beta_j(u) := (\lambda_j^2 + 2\beta_j(u))^{1/2} \in (0, 1]. \text{ Now } -\log R_j(u) = 12 \log(1 + 2\beta_j(u)\lambda_j) \leq \beta_j(u)\lambda_j \leq \frac{1}{2} \lambda_j^2. \text{ Now } -\log R_j(u) = 12 \log(1 + 2\beta_j(u)\lambda_j) \leq \beta_j(u)\lambda_j \leq \frac{1}{2} \lambda_j^2.$$

$R_j(u) = \frac{1}{2} \log \left(1 + \frac{\beta_j(u)}{\lambda_j} \right)$. Hence $\sum_j |\log R_j(u)| < \infty$, so $\Phi_N(u) \rightarrow \Phi^\infty(u) \in (0, 1] \setminus \Phi_N(u) \cup \Phi_\infty(u) \in (0, 1]$. By coercivity of $P_m P_m$ and $|\Phi_N| \leq 1 / \Phi_N$, $\mathcal{N}_N(F) \leq \|F\|_\infty e^{-\eta P_m(u)}$. Thus dominated convergence gives $\mathcal{N}_N(F) \rightarrow \mathcal{N}_\infty(F) = \mathcal{N}_\infty(F) \mathcal{N}_N(F) \mathcal{N}_\infty(F)$. Assuming $D_\infty \neq 0$, ratios converge.

For the rate, write $\Phi N' = \Phi N \Psi N, N' \Phi_{\{N'\}} = \Phi_{\{N\}} \Psi_{\{N, N'\}}$,
 $\Psi N, N' := \prod j=N+1^N R_j \Psi_{\{N, N'\}} := \prod_{j=N+1}^N \{N'\} R_j$. Because
 $0 < R_j \leq 10 < R_j \leq 1$, $1 - \Psi N, N' \leq \sum j=N+1^N (1 - R_j) \cdot 1 - \Psi_{\{N, N'\}} \leq \sum_{j=N+1}^N \{N'\} (1 - R_j)$. Set $t_j = 2\beta_j / j \geq 0$. Since $1 - (1+t)^{-1/2} \leq t_1 - (1+t)^{-1/2}$, $t_j \leq t$ for $t \geq 0$, $1 - R_j(u) \leq 2\beta_j(u) / j \leq 2 / u \cdot 2A_j \lambda_j \cdot 1 - R_j(u) \leq \frac{2\beta_j(u)}{\lambda_j} \leq 2 / u \cdot \frac{2A_j}{\lambda_j}$. Therefore $|\Phi N'(u) - \Phi N(u)| \leq 2 / u \cdot \sum_{j=N+1}^N A_j \lambda_j \cdot |\Phi_{\{N'\}}(u) - \Phi_{\{N\}}(u)| \leq 2 / u \cdot \sum_{j=N+1}^N \{N'\} \frac{A_j}{\lambda_j}$. Insert this bound in \mathcal{N}, \mathcal{D} differences and use $|e^{-(\eta-i/\varepsilon)P_m}| \leq e^{-\eta P_m} e^{-\{-(\eta-i/\varepsilon)P_m\}} \leq e^{-\{-(\eta-i/\varepsilon)P_m\}}$. Then for $C_1 := 2 \int e^{-\{-(\eta-i/\varepsilon)P_m\}} du < \infty$, $|\mathcal{N}N'(F) - \mathcal{N}N(F)| \leq \|F\| \infty C_1 \sum_{j=N+1}^N A_j \lambda_j \cdot |\mathcal{N}_{\{N'\}}(F) - \mathcal{N}_{\{N\}}(F)| \leq \|F\| \infty C_1 \sum_{j=N+1}^N \{N'\} \frac{A_j}{\lambda_j} \cdot |\mathcal{D}N' - \mathcal{D}N| \leq C_1 \sum_{j=N+1}^N A_j \lambda_j \cdot |\mathcal{D}N| \leq C_1 \sum_{j=N+1}^N \{N'\} \frac{A_j}{\lambda_j} \cdot |\mathcal{D}N| \geq d^* > 0$, and $|a'b' - ab| \leq |a-a'||b'-b| + |a||b'-b| \leq \frac{|a'|}{|b'|} |b'| + |a||b'| \leq \frac{|a'|}{|b'|} + |a||b'|$ gives the stated rate. \square

Partition-Factor Non-Vanishing Bounds

Theorem 16 (Moment criteria). Let $A\eta = \int e^{-\eta S(x)} dx \in (0, \infty)$ and $Z_{\varepsilon, \eta} := \int e^{-(\eta - i/\varepsilon)S(x)} dx = A\eta \mathbb{E}_{\mu\eta}[e^{iS/\varepsilon}]$, $\mu\eta(dx) := e^{-\eta S(x)} A\eta dx$. Then $\mathbb{E}_{\mu\eta}[e^{\lambda S}] = \int e^{\lambda S(x)} \mu\eta(dx) = \int e^{\lambda S(x)} e^{-\eta S(x)} A\eta dx = A\eta \mathbb{E}_{\mu\eta}[e^{(\lambda - \eta)S}]$. Define $M_1 := \mathbb{E}\mu\eta[S]$, $M_2 := \mathbb{E}\mu\eta(S^2)$, $M_1' := \mathbb{E}_{\mu\eta}[S]$, $M_2' := \mathbb{E}_{\mu\eta}[S^2]$. Then $|Z_{\varepsilon, \eta}| \geq A\eta(1 - M_1\varepsilon)$, $|Z_{\varepsilon, \eta}| \geq A\eta(1 - M_2\varepsilon^2)$, $|Z_{\varepsilon, \eta}| \geq A\eta(1 - \frac{M_1}{M_2}\varepsilon^2)$. Hence if $\varepsilon > M_1/M_2$ or $\varepsilon^2 > M_2/2$, then $Z_{\varepsilon, \eta} \neq 0$.

Proof. First bound: $|\mathbb{E}[eiX]| = |1 + \mathbb{E}(eiX - 1)| \geq 1 - \mathbb{E}|eiX - 1|, X = S/\varepsilon.$ Since $|\mathbb{E}[e^{iX}]| = |1 + \mathbb{E}(e^{iX} - 1)| \geq 1 - \mathbb{E}|e^{iX} - 1|, \quad X = S/\varepsilon.$ Since $|e^{it} - 1| \leq |t| |e^{it} - 1| / |t|, |\mathbb{E}[eiS/\varepsilon]| \geq 1 - M_1 \varepsilon.$ Multiply by $A \eta A^{-1}$.

Second bound: $\Re \mathbb{E}[e^{iS/\varepsilon}] = \mathbb{E}[\cos(S/\varepsilon)] \geq 1 - 12\mathbb{E}[(S/\varepsilon)^2] = 1 - M_2 \varepsilon^2 / \Re z$
 $\mathbb{E}[e^{iS/\varepsilon}] = \mathbb{E}[\cos(S/\varepsilon)] \geq 1 - \frac{1}{2} / \mathbb{E}[(S/\varepsilon)^2] = 1 - \frac{M_2}{2\varepsilon^2}$. Now $|z| \geq Rz|z| \geq \Re z$ gives the inequality for $|Z_{\varepsilon,n}| / |Z_{\varepsilon,n}| \leq \frac{1}{\varepsilon}$. \square

Observable-Class Extension

Theorem 17 (Continuity on Schwartz and weighted Sobolev classes). Let $\mathcal{I}(F) = \int \mathbb{R} dei\Phi(y)W(y)F(Ay)dy$, $\mathcal{I}(F) = \int e^{\langle R^d, F \rangle} dy$, with $A \in GL(d, \mathbb{C})$ in $GL(d, \mathbb{C})$ and $|W(y)| \leq C_0 e^{-c_4/|y|^4 + c_2/|y|^2}$, $c_4 > 0$. Then:

1. for every integer $k > dk > d$, there exists CkC_k such that $|\mathcal{I}(F)| \leq Cksupx(1+|x|)^k |F(x)|, F \in \mathcal{S}(\mathbb{R}^d); |\mathcal{I}(F)| \leq C_k \sup_x (1+|x|)^k |F(x)|, F \in \mathcal{S}(R^d)$;
2. for every $k > d/2k > d/2$, there exists $Ck'c_k$ such that $|\mathcal{I}(F)| \leq Ck'(1+|x|)^{2k} |F(x)|, F \in H^0(k), |\mathcal{I}(F)| \leq C_k' (1+|x|)^{2k} |F(x)|, F \in H^0(k)$.

Consequently, normalized functionals $\omega(F) = \mathcal{I}(F)/\mathcal{I}(1)$, $\omega(F) = \mathcal{I}(F)/\mathcal{I}(1)$ (when $\mathcal{I}(1) \neq 0$) extend continuously from Gaussian-polynomial test families to both classes.

Proof. For Schwartz: $|F(Ay)| \leq CApk(F)(1+|y|)^{-k}, pk(F) := \sup_x (1+|x|)^k |F(x)|$, $|F(Ay)| \leq C_A p_k(F)(1+|y|)^{-k}$, $p_k(F) := \sup_x (1+|x|)^k |F(x)|$. Hence $|\mathcal{I}(F)| \leq C_0 CApk(F) e^{-c_4/|y|^4 + c_2/|y|^2} (1+|y|)^{-k} dy$, $|\mathcal{I}(F)| \leq C_0 C_A p_k(F) \int e^{-c_4/|y|^4 + c_2/|y|^2} (1+|y|)^{-k} dy$, and the integral is finite.

For weighted Sobolev: $|\mathcal{I}(F)| \leq \|W(\cdot)(1+|y|)^2 - k/2\| L^2 \| (1+|y|)^k F(Ay) \|_{L^2}$, $|\mathcal{I}(F)| \leq \|W(\cdot)(1+|y|)^2\|_{L^2} \| (1+|y|)^k F(Ay) \|_{L^2}$. The first factor is finite by quartic decay; the second is bounded by $CA'/F/H^0(k)C_A \|F\|_{H^0(k)}$ after linear change of variables. \square

Schwinger-Dyson and $\tau\mu\backslash\tauau_\mu$ Scale Covariance

Theorem 18 (Finite-dimensional Schwinger-Dyson identity). Let $c = \eta - i/\epsilon$, $\mathcal{I}_c(F) := \int e^{-cS(x)} F(x) dx$. Assume integrability and vanishing boundary flux for admissible F and vector field V . Then $\mathcal{I}_c(V \cdot \nabla S F) = 1/c \mathcal{I}_c(\nabla \cdot (VF))$, $\mathcal{I}_c(V \cdot \nabla S F) = \frac{1}{c} \mathcal{I}_c(\nabla \cdot (VF))$. If $\mathcal{I}_c(1) \neq 0$, then $\omega_c(V \cdot \nabla S F) = 1/c \omega_c(\nabla \cdot (VF))$, $\omega_c(V \cdot \nabla S F) = \frac{1}{c} \omega_c(\nabla \cdot (VF))$. In particular, for constant $V = eiV = e_i$ and $F \equiv 1$, $\omega_c(\partial_i S) = 0$, $\omega_c(\partial_i S) = 0$.

Proof. $0 = \int \nabla \cdot (e - cSVF) dx = \int e - cS(\nabla \cdot (VF) - cV \cdot \nabla SF) dx$. $0 = \int \nabla \cdot (e - cSVF) dx = \int e^{-cS} (\nabla \cdot (VF) - cV \cdot \nabla SF) dx$. Rearrange, then divide by $\mathcal{I}_c(1)$ for the normalized form. \square

Theorem 19 (Exact $\tau\mu\backslash\tauau_\mu$ covariance). For $\omega_\kappa, \eta, h(F) := \int e^{-(\eta - i/h)\kappa S(x)} F(x) dx$, $\omega_{\kappa, \eta, h}(F) := \frac{1}{c} \int e^{-(\eta - i/h)\kappa S(x)} F(x) dx$,

define $\tau\mu:(\kappa,\eta,h)\mapsto(\mu\kappa,\eta/\mu,\mu h)$, $\mu>0$. $\tau\mu$:
 $\kappa\mapsto\mu\kappa$, $\eta\mapsto\eta/\mu$, $h\mapsto\mu h$. Then $\omega\kappa,\eta,h(F)=\omega\tau\mu(\kappa,\eta,h)(F)$. $\omega\tau\mu(\kappa,\eta,h)(F)=\omega\kappa,\eta,h(F)$.

Proof. Directly, $(\eta\mu-i\mu h)(\mu\kappa)=(\eta-i/h)\kappa \cdot \left(\frac{\eta}{\mu}\right) \cdot \left(\frac{i}{\mu h}\right)$. Hence numerator and denominator kernels are unchanged. \square

Dependency Chain

The proofs in this manuscript now close in the following order:

1. Sections 2–5: core scoped Claim 1 closure.
2. Theorem 15: large-NN coupled extension with explicit tail rate.
3. Theorem 16: explicit non-vanishing criteria for partition factors.
4. Theorem 17: observable-class extension to Schwartz/Sobolev.
5. Theorems 18 and 19: Schwinger-Dyson identities and exact scale-flow covariance.

Conclusion

This manuscript now gives a theorem-grade chain from the static/finite-dimensional variational-delta picture to a broad scoped family of oscillatory states including:

1. exact projective closure and de-regularization,
2. explicit semiclassical channel expansion,
3. large-NN mode-coupled convergence with quantitative tail control,
4. non-vanishing control for normalization factors,
5. extension to large observable classes,
6. Schwinger-Dyson identities and scale-flow covariance.

Open frontier (outside this closure): full interacting, non-factorized, genuinely field-theoretic continuum limits with uniform renormalization control beyond the scoped polynomial block-tail class.
