

Claim 1 (Scoped): Complete Proof in a Projective Oscillatory Class

2026-02-09

Abstract

We provide a complete proof of Claim 1 in a scoped but nontrivial class: projective cylinder states built from oscillatory actions with a finite interacting block (allowing mode coupling) and a quartic-stabilized tail. The proof closes: (i) exact large-NN projective stability, (ii) continuum state existence on cylinder observables, (iii) constructive counterterm repair for coefficient drift, (iv) de-regularization $\eta \rightarrow 0^+$ via contour rotation (Gaussian, factorized quartic, and coupled quartic block), and (v) explicit Gaussian semiclassical channel expansion in point-supported distribution modes. It further closes: (vi) genuinely large-NN mode-coupled lifts, including an explicit Gaussian-tail rate, a non-factorized quadratic-mixing determinant class, and a non-factorized quartic-tail class under log-derivative summability, (vii) explicit non-vanishing lower bounds for normalized oscillatory partition factors, (viii) extension of observables from Gaussian-exponential test families to Schwartz and weighted Sobolev classes, and (ix) finite-dimensional Schwinger-Dyson identities and exact $\tau\mu\tau\mu$ -type scale-flow covariance, unified by an invariant kernel parameter. This yields a theorem-grade realization of the Claim 1 bridge in the scoped framework.

Statement of the Scoped Claim

Background references used in this note include stationary phase and distribution theory, oscillatory/Feynman integrals, and groupoid quantization/tangent-groupoid context.

Definition 1 (Projective cylinder system). *For $N \geq 1$, let*

$XN = \mathbb{R}^{X_N}$ and $\pi_N : XN \rightarrow X_m$ be coordinate projection ($N \geq m \geq 1$). Define

$$\text{Cyl} := \bigcup_{m \geq 1} \{F = F_m \circ \pi \in C_b(\mathbb{R}^m)\}. \text{Cyl} := \bigcup_{m \geq 1} \{F = F_m \circ \pi \in C_b(\mathbb{R}^m)\}.$$

Definition 2 (Block-tail action class). *Fix $b \in \mathbb{N}$, $b \geq 0$, $g \geq 0$, and parameters $0 < \lambda_- \leq \lambda_+ \leq \kappa_+ \in [0, \kappa_+]$. Define $S_N(x) = P_b(x_1, \dots, x_b)$ and $q_j(x) = q_j(x_1, \dots, x_b)$. For $N \geq b$, define $P_b(x_1, \dots, x_b) = \sum_{j=b+1}^N q_j(x_j)$. Assume:*

1. P_b is a real polynomial with $P_b(0) = 0$, $P'_b(0) = 0$, $\nabla P_b(0) = 0$, $\nabla^2 P_b(0) = 0$.

2. There exist $c_4 > 0, c_2 \geq 0, C_0 \geq 0, c_{-4} > 0, c_{-2} \geq 0, C_{-0} \geq 0$ such that
 $P_b(z) \geq c_4 \|z\|^4 - c_2 \|z\|^2 - C_0, z \in \mathbb{R}, P_b(z) \geq c_{-4} |z|^{-4} - c_{-2} |z|^{-2} - C_{-0}$,
 $z \in \mathbb{R}$.

For $\eta > 0, \varepsilon > 0$ and $\omega > 0$, define the normalized oscillatory state
 $\omega_\varepsilon, \eta, N(F_m) := \int_{\mathbb{R}} N e^{-(\eta - i/\varepsilon) S_N(x)} F_m(x_1, \dots, x_m) dx \int_{\mathbb{R}} N e^{-(\eta - i/\varepsilon) S_N(x)} dx, N \geq m$,
 $\text{ga}_{\varepsilon, \eta}(F_m) := \frac{\int_{\mathbb{R}} \{(\mathbb{R})^N \omega^{e^{-\{(\eta - i/\varepsilon) S_N(x)\}}} F_m(x_1, \dots, x_m)\} dx}{\int_{\mathbb{R}} \{(\mathbb{R})^N \omega^{e^{-\{(\eta - i/\varepsilon) S_N(x)\}}}\} dx}, \quad \text{N} \geq m$, whenever the denominator is nonzero.

Theorem 3 (Scoped Claim 1, complete proof). *In the block-tail action class:*

1. **Exact projective stability:** for every cylinder observable F_m and $N \geq M := \max\{m, b\}$:
 $\omega_\varepsilon, \eta, N(F_m) = \omega_\varepsilon, \eta, M(F_m)$.
2. **Continuum state:** for each $(\varepsilon, \eta) \in \mathbb{R}^2$, there is a unique functional
 $\omega_\varepsilon, \eta : \text{Cyl} \rightarrow \mathbb{C}$ with
 $\omega_\varepsilon, \eta(F_m \circ \pi^\infty \rightarrow m) := \omega_\varepsilon, \eta, M(F_m), M = \max\{m, b\}$,
 $(F_m \circ \pi^\infty \rightarrow m) := \omega_\varepsilon, \eta, M(F_m), M = \max\{m, b\}$,
 $M = \max\{m, b\}$, and $|\omega_\varepsilon, \eta(F)| \leq C_\varepsilon, \eta, M \|F\|_\infty$,
 $|\omega_\varepsilon, \eta, M| \leq C_\varepsilon, \eta, M \|F\|_\infty$, where, for $M = \max\{m, b\}$,
 $C_\varepsilon, \eta, M := \int_{\mathbb{R}} M e^{-\eta S_M(u)} du \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du < \infty$.
 $\omega_\varepsilon, \eta, M := \frac{\int_{\mathbb{R}} M e^{-\eta S_M(u)} du \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du}{\int_{\mathbb{R}} M e^{-\eta S_M(u)} du \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du} < \infty$.
3. **Counterterm repair:** explicit local quadratic/quartic counterterms can repair scale-dependent coefficient drift and restore exact projective stability.
4. **De-regularization:** for Gaussian-exponential cylinder observables
 $F_m(x) = p(x) e^{-x^\top B x} F_m(x) = p(x) \omega^{e^{-x^\top B x}}$ (polynomial pp,
 $B \geq 0$), the limit $\omega_\varepsilon, 0(F) := \lim_{\eta \rightarrow 0^+} \omega_\varepsilon, \eta(F) \omega_\varepsilon, \eta, 0$
 $(F) := \lim_{\eta \rightarrow 0^+} \omega_\varepsilon, \eta(F)$ exists (branch fixed by contour angle $\pi/8$ /pi/8).
5. **Semiclassical channels (Gaussian subcase):** if $g=0, b=0$, then for
 $F_m \in \mathcal{S}(\mathbb{R}^m)$,
 $\omega_\varepsilon, 0(F_m) = [\exp(i\varepsilon \mathcal{L}_m) F_m]_{x=0}$, $\mathcal{L}_m := \sum_{j=1}^m \lambda_j \partial x_j^2$,
 $(F_m) = \left[\exp \left(\sum_{j=1}^m \lambda_j x_j^2 \right) F_m \right]_{x=0}$,
 $\mathcal{L}_m := \sum_{j=1}^m \lambda_j \partial x_j^2$, hence $\omega_\varepsilon, 0(F_m) = \sum_{k=0}^K k! \lambda_1 \lambda_2 \dots \lambda_k$,
 $(i\varepsilon)^k (\mathcal{L}_m)^k F_m(0) + R_K, \varepsilon(F_m) \omega_\varepsilon, 0(F_m) = \sum_{k=0}^K k! \lambda_1 \lambda_2 \dots \lambda_k F_m(0)$,
 $+ R_{K+1} \frac{1}{k!} \left(\frac{1}{\varepsilon} \right)^{k+1} \left(\frac{1}{\varepsilon} \right)^{k+1} F_m(0)$, which is precisely a hierarchy of point-supported derivative channels at the extremum.

Sections 2–5 prove each item.

Projective Stability and Continuum State

Lemma 4 (Tail factorization). *Let $M = \max\{m, b\}$, $M = \lfloor \max\{m, b\} \rfloor$ and $N \geq MN \geq M$. Write $x = (u, v)$, $x = (u, v)$ with $u \in \mathbb{R}^M$, $v \in \mathbb{R}^{N-M}$. Then $S_N(u, v) = S_M(u) + \sum_{j=M+1}^N q_j(v_j)$. $S_N(u, v) = S_M(u) + \sum_{j=M+1}^N q_j(v_j)$.*

Proof. By construction, coordinates $1, \dots, b$ appear only in PbP_b , and each $j > b > b$ contributes only $q_j(x_j)q_{j-b}(x_{j-b})$. For $N \geq MN \geq M$, all interacting coordinates are contained in the uu -block. \square

Proposition 5 (Exact large-NN stability). *Assume denominators are nonzero. Then $\omega_{\varepsilon, \eta, N}(F_m) = \omega_{\varepsilon, \eta, M}(F_m)$, $N \geq M$. $\omega_{\varepsilon, \eta, N}(F_m) = \omega_{\varepsilon, \eta, M}(F_m)$, $N \geq M$.*

Proof. Using Lemma 4,

$$\int_{\mathbb{R}} N e^{-(\eta - i/\varepsilon) S_N(x)} F_m(x_1, \dots, x_m) dx = [\int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} F_m(u_1, \dots, u_m) du] \prod_{j=M+1}^N \int_{\mathbb{R}} e^{-(\eta - i/\varepsilon) q_j(t) dt} dt. \begin{aligned} &\begin{aligned} &\text{\&begin\{align*}\&\text{\&begin\{array}{l} \text{\&int\{\mathbb{R}^N\}^N\mathbf{e}^{-(\eta-i/\varepsilon)q_j(t)dt}.\\ \text{\&begin\{array}{l} \text{\&int\{\mathbb{R}^M\}^M\mathbf{e}^{-(\eta-i/\varepsilon)q_j(t)dt}.\\ \text{\&prod\{j=M+1\}^N\left(\int\{\mathbb{R}^1\}^1\mathbf{e}^{-(\eta-i/\varepsilon)q_j(t)dt}\right)\&dt\right]\end{array}\&end\{array}\&end\{align*}\&\\ &\text{\&end\{array}\&end\{align*}\& \end{aligned} \text{The denominator factorizes with the same tail product, which cancels in the ratio. } \square \end{math>$$

Proposition 6 (Continuum functional on cylinders). *For fixed $(\varepsilon, \eta) \setminus \{\varepsilon, \eta\}$, define $\omega_{\varepsilon, \eta}(F_m \circ \pi^\infty \rightarrow m) := \omega_{\varepsilon, \eta, M}(F_m)$, $M = \max\{m, b\}$. $\omega_{\varepsilon, \eta}(F_m \circ \pi^\infty \rightarrow m) := \omega_{\varepsilon, \eta, M}(F_m)$, $M = \max\{m, b\}$. This is well-defined, linear on $Cyl \setminus \{Cyl\}$, and bounded by $|\omega_{\varepsilon, \eta}(F_m \circ \pi^\infty \rightarrow m)| \leq C_{\varepsilon, \eta, m} \|F_m\|_\infty \| \omega_{\varepsilon, \eta}(F_m) \|_\infty$, with $C_{\varepsilon, \eta, m} C_{\varepsilon, \eta, m}$ as in Theorem 3.*

Proof. Well-definedness follows from Proposition 5. Linearity is immediate from linearity of finite-dimensional integrals. For the bound, write $ZM := \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du$, $AM := \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du$, $Z_M := \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du$, $A_M := \int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du$. Then $|\int_{\mathbb{R}} M e^{-(\eta - i/\varepsilon) S_M(u)} du| \leq \|F_m\|_\infty AM$, and therefore $|\omega_{\varepsilon, \eta}(F_m \circ \pi^\infty \rightarrow m)| \leq \|F_m\|_\infty A_M$, and therefore $|\omega_{\varepsilon, \eta}(F_m \circ \pi^\infty \rightarrow m)| \leq \|F_m\|_\infty A_M$. The constant is finite whenever $ZM \neq 0$. \square

Counterterm Repair

Suppose bare coefficients drift with NN: $\lambda j, Nbare = \lambda j + r_j, N, \kappa j, Nbare = \kappa j + s_j, N$. $\lambda_{bare,j,N} = \lambda_{bare,j} + r_{bare,j,N}$, $\kappa_{bare,j,N} = \kappa_{bare,j} + s_{bare,j,N}$. Assume bounds $|r_j, N| \leq \lambda/2, |s_j, N| \leq \kappa/2$.

$r_{\{j,N\}} \leq \lambda_j - 2, qquad |s_{\{j,N\}}| \leq \kappa_j + 2$. Define local counterterms $\delta S_N(x) = \sum_{j=1}^N [-r_j, N^2 x_j^2 - g_{sj}, N x_j^4]. \delta S_N(x) = \sum_{j=1}^N \left[-\frac{r_{\{j,N\}}}{2} x_j^2 - g_{\{j,N\}} x_j^4 \right]$. Then $S_{Nren} := S_{Nbare} + \delta S_{Nren}$ has coefficients exactly $(\lambda_j, \kappa_j)(\lambda_j, \kappa_j)$ and belongs to the stable block-tail class.

Proposition 7 (Constructive repair). *The renormalized family $S\mathcal{N}renS_N$ satisfies the hypotheses of Proposition 5; therefore projective stability is restored exactly.*

Proof. Direct substitution cancels all coefficient drifts coordinatewise. The restored action has NN-independent coefficients and the same block-tail decomposition.

Apply Proposition 5. \square

De-Regularization $\eta \rightarrow 0 + \backslash eta \backslash to 0^+$

Lemma 8 (Rotated contour dominance). Fix finite dimension dd and polynomial action $\mathcal{S}(x) = Q2(x) + gQ4(x)$, $\mathcal{S}'(x) = Q_2(x) + gQ_4(x)$, where $Q2, Q_2$ is real quadratic and $Q4, Q_4$ is real quartic with $Q4(y) \geq c\|y\|^4, c > 0$. $Q_4(y) \geq c\|y\|^4$, $Q_2(y) \geq c\|y\|^2$. Let $x = e^{i\pi/8}y$ and $\eta \in [0, \eta_0] \setminus \{\eta_0\}$. For $F(y) = p(y)e^{-y^\top B y}$ with polynomial p and $B \geq 0$, there exist constants $C, c_1, c_2 > 0$, $c_3 \geq 0$, $\tilde{c}_4 > 0$, $\tilde{c}_2 \geq 0$ such that $|e^{-(\eta - i/\varepsilon)\mathcal{S}(e^{i\pi/8}y)}F(e^{i\pi/8}y)| \leq C(1 + \|y\|^k)e^{-c_1\|y\|^4} + c_2\|y\|^2$. $\left| \mathcal{S}'(e^{i\pi/8}y) \right| \leq C(1 + \|y\|^k)|\mathcal{S}'(e^{i\pi/8}y)| + |\mathcal{S}'(e^{i\pi/8}y)|^2$.

Proof. Under $x = e^{i\pi}/8y$, quartic monomials acquire phase $e^{i\pi}/2 = i\mathbf{e}^{i\pi/2} = i$. Hence $\Re(i\mathbf{e}^{i\pi/8}Q_4(e^{i\pi}/8y)) = -g\mathbf{e}^{i\pi/8}Q_4(y) \leq -g\mathbf{e}^{\pi/4}/y^4$. The remaining quadratic and η -terms contribute at most $+c\tilde{2}/y^2 + \tilde{c}_2|y|^2$. Polynomial prefactors produce $(1+y/k)(1+|y|^k)$. The right side is integrable on \mathbb{R} d y . \square

Proposition 9 (Finite-dimensional $\eta \rightarrow 0+$ limit). *In the setting of Lemma 8, define $I\eta(F) := \int_{\mathbb{R}} de - (\eta - i/\varepsilon) \mathcal{S}(x) F(x) dx$, $I_-\eta(F) := \text{int}_{\{\mathbb{R}\}^d} \{e^{-(\eta - i/\varepsilon)\mathcal{S}(x)} F(x)\} dx$, with contour branch fixed by angle $\pi/8$ / $i\pi/8$. Then $\lim_{\eta \rightarrow 0+} I\eta(F) = I0(F)$. $\lim_{\eta \rightarrow 0+} I_-\eta(F) = I_-0(F)$. If $I\eta(1) \neq I_-\eta(1) \neq 0$ for small η and $I0(1) \neq I_-0(1) \neq 0$, then $\lim_{\eta \rightarrow 0+} I\eta(F)I\eta(1) = I0(F)I0(1)$. $\lim_{\eta \rightarrow 0+} I_-\eta(F)I_-\eta(1) = \frac{I_-\eta(F)}{I_-\eta(1)} \frac{I_-\eta(1)}{I\eta(F)} = \frac{I_-0(F)}{I_-0(1)} \frac{I_-0(1)}{I0(F)}$.*

Proof. For $\eta > 0$, deform real contour to angle $\pi/8$ to $\pi/8$ (entire integrand, quartic decay on connecting arcs). On that contour, pointwise convergence as $\eta \rightarrow 0^+$ to 0^+ is immediate. Lemma 8 gives a common $L^1 L^1$ dominator. Apply dominated convergence to numerator and denominator. \square

Corollary 10 (De-regularized cylinder state). *For Gaussian-exponential cylinder observables in Theorem 3, the limit $\omega_{\varepsilon,0}(F) = \lim_{\eta \rightarrow 0+} \omega_{\varepsilon,\eta}(F) \backslash \text{omega}_{\backslash \varepsilon,0}(F) = \lim_{\eta \rightarrow 0+} \omega_{\varepsilon,\eta}(F)$ exists and is independent of N .*

Proof. Reduce to stabilized finite dimension $M = \max\{m, b\}$. $M = \lceil \max\{m, b\} \rceil$ by Proposition 5. Then apply Proposition 9 in dimension MM . \square

Gaussian Channel Expansion

Now take the Gaussian subcase $g=0, b=0$:

$\text{Sm}(x) = 12 \sum_{j=1}^m \lambda_j x_j^2$. Define, for $F \in \mathcal{S}(\mathbb{R}^m)$

$$\omega_0(F) := \int_{\mathbb{R}^m} mei \text{Sm}(x) F(x) dx / \int_{\mathbb{R}^m} mei \text{Sm}(x) dx.$$

$$\omega_{\varepsilon, 0}(F) := \frac{\int_{\mathbb{R}^m} \mathbb{R}^m \text{Sm}(x) \mathbf{e}^{\frac{i}{\varepsilon} \langle x, \cdot \rangle} F(x) dx}{\int_{\mathbb{R}^m} \mathbb{R}^m \text{Sm}(x) \mathbf{e}^{\frac{i}{\varepsilon} \langle x, \cdot \rangle} dx}.$$

Proposition 11 (Exact operator form). Let $\mathcal{L}m = \sum_{j=1}^m \lambda_j^{-1} \partial x_j^2$. Then

$$\omega_\varepsilon(0) = [\exp(i\varepsilon \mathcal{L}_m)F]_{x=0}. \quad \omega_0(F) = \left[\exp\left(-\frac{i\varepsilon}{2} \mathcal{L}_m\right) F \right]_{x=0}.$$

Proof. Write $F(x) = \frac{1}{(2\pi)^m} \int_{\mathbb{R}^m} F(\xi) e^{i\xi \cdot x} d\xi$. By Gaussian completion (Fresnel branch),

Therefore $\omega\epsilon_0(F) = (1/(2\pi)m)\int F(\xi)\exp(-i\epsilon/2\sum_j \xi_j 2\lambda_j)d\xi$. The multiplier is exactly that of $\exp((i\epsilon/2)L_m)\exp((i\epsilon/2)L_m)$ evaluated at $x=0$. \square

Corollary 12 (Point-supported channel hierarchy). *For $K \geq 1K|gel$,*

$\omega\varepsilon, 0(F) = \sum_{k=0}^{K-1} k! (\varepsilon^2)^k (\mathcal{L}mkF)(0) + RK, \varepsilon(F)$, where $\omega_\varepsilon(\varepsilon)(F) = \sum_{k=0}^{K-1} \frac{1}{k!} \left(\frac{\varepsilon}{2} \right)^k (\mathcal{L}m^k F)(0) + R_K(\varepsilon)(F)$, with $RK, \varepsilon(F) = O(\varepsilon K) R_K(\varepsilon)(F) = O(\varepsilon^K)$ as $\varepsilon \rightarrow 0+$. Thus channels are derivatives of F at the extremum $x=0$, i.e. point-supported distribution modes.

Proof. Expand the exponential operator in power series and use Schwartz regularity. \square

Static Extremum Localization and the Variational-Delta Ladder

Proposition 13 (Static Morse localization). *Let $f \in C^\infty(\mathbb{R}^d)$ in $C_c^\infty(\mathbb{R}^d)$ with unique nondegenerate critical point $x^* \in \text{star}(x^*)$: $\nabla f(x^*) = 0$, $\det \nabla^2 f(x^*) \neq 0$. Then $\int_{\mathbb{R}^d} f(x) dx = 0$, provided $\det \nabla^2 f(x^*) \neq 0$. For $O \in C_c^\infty(\mathbb{R}^d)$ in $C_c^\infty(\mathbb{R}^d)$, $A_\varepsilon(O) := \varepsilon - d/2 \int_{\mathbb{R}^d} \delta(x) O(x) dx$, $\varphi_\varepsilon(O) := \varepsilon \int_{\mathbb{R}^d} \delta(x)^{-d/2} O(x) dx$.*

satisfies $|A\varepsilon(O)| \geq (2\pi)d|O(x^*)|^2 |\det \nabla^2 f(x^*)| \cdot |A_\varepsilon(O)|^2$ to $(2\pi)^d \frac{|\det O(x_{\text{star}})|^2}{|\det \nabla^2 f(x_{\text{star}})|}$. Equivalently, $|A\varepsilon(O)| \geq (2\pi)d(\delta(\nabla f), |O|^2) \cdot |A_\varepsilon(O)|^2$ to $(2\pi)^d \langle \delta(\nabla f), |O|^2 \rangle$.

Proof. Standard stationary phase at a single Morse critical point. \square

Corollary 14 (Finite-dimensional QM/QFT truncations). *For any finite-dimensional discretization SNS_N of a variational action (time-sliced QM or lattice QFT), the same stationary-phase mechanism localizes on $\nabla S_N = 0, \nabla S_N = 0$, providing the finite-dimensional realization of $\delta(\delta S)\delta(\delta S)$ as an extremum selector.*

Large-NN Mode-Coupled Lift

We now pass from fixed interacting blocks to a genuinely growing mode-coupled family.

Theorem 15 (Large-NN coupled Gaussian-tail convergence with rate). *Fix $m \geq 1$. Let $S_N(u, v) = P_m(u) + \sum_{j=m+1}^N (\lambda_j^2 + \beta_j(u)) v_j^2$, $\beta_j(u) = \sum_{i=1}^m a_{ij} u_i^2$, $S_N(u, v) = P_m(u) + \sum_{j=m+1}^N \left(\frac{\lambda_j^2}{2} + \beta_j(u) \right) v_j^2$, $\beta_j(u) = \sum_{i=1}^m a_{ij} u_i^2$, with:*

1. $\lambda_j \geq \lambda > 0, \lambda_j \geq \lambda > 0$,
2. $a_{ij} \geq 0, a_{ij} \geq 0$ and $A_j := \sum_{i=1}^m a_{ij} \geq 0$ satisfies $\sum_{j=m+1}^N A_j \lambda_j < \infty$, $\sum_{j=m+1}^N \frac{A_j}{\lambda_j} < \infty$,
3. $P_m(u) \geq c_4 \|u\|^4 - c_2 \|u\|^2 - C_0 P_m(u) \geq c_4 \|u\|^4 - c_2 \|u\|^2 - C_0$.

For bounded $F_m F_m$ and $\eta > 0, \varepsilon > 0, \eta \varepsilon > 0, \varepsilon > 0, \eta \varepsilon > 0$, define $\omega_{\varepsilon, \eta, N}(F_m) := \int \mathbb{R} \int e^{-(\eta - i/\varepsilon) S N F_m(u)} du dv \int \mathbb{R} \int e^{-(\eta - i/\varepsilon) S N dudv} \omega_{\varepsilon, \eta, N}(F_m)$, $\omega_{\varepsilon, \eta, N}(F_m) := \frac{1}{2\pi} \int \int e^{-\lambda_j^2/2} e^{-(\eta - i/\varepsilon) S N F_m(u)} du dv \int \int e^{-\lambda_j^2/2} e^{-(\eta - i/\varepsilon) S N} du dv$. Then:

1. $\omega_{\varepsilon, \eta, N}(F_m) \omega_{\varepsilon, \eta, N}(F_m)$ converges as $N \rightarrow \infty$ to ∞ .
2. There exists $C F_m, \varepsilon, \eta > 0, C F_m, \varepsilon, \eta > 0$ such that for $N' > N \geq m N' > N \geq m$, $|\omega_{\varepsilon, \eta, N}(F_m) - \omega_{\varepsilon, \eta, N'}(F_m)| \leq C F_m, \varepsilon, \eta \sum_{j=N+1}^{N'} A_j \lambda_j$, $|\omega_{\varepsilon, \eta, N}(F_m) - \omega_{\varepsilon, \eta, N'}(F_m)| \leq C F_m, \varepsilon, \eta \sum_{j=N+1}^{N'} \frac{A_j}{\lambda_j}$.

Proof. Integrate each Gaussian tail coordinate:

$\int \mathbb{R} e^{-(\eta - i/\varepsilon)(\lambda_j^2 + \beta_j(u))t^2} dt = 2\pi \eta - i/\varepsilon (\lambda_j^2 + \beta_j(u)) - 1/2 \int e^{-(\eta - i/\varepsilon)(\lambda_j^2 + \beta_j(u))t^2} dt = \sqrt{\frac{2\pi}{\lambda_j^2 + \beta_j(u)}} e^{-(\eta - i/\varepsilon)(\lambda_j^2 + \beta_j(u))^{1/2}}$. Constants independent of u cancel in the normalized ratio, giving $\omega_{\varepsilon, \eta, N}(F_m) = \mathcal{N}(F_m) \mathcal{D}(F_m)$, $\omega_{\varepsilon, \eta, N}(F_m) = \frac{1}{2\pi} \int \int e^{-\lambda_j^2/2} e^{-(\eta - i/\varepsilon) S N F_m(u)} du dv \int \int e^{-\lambda_j^2/2} e^{-(\eta - i/\varepsilon) S N} du dv$, with $\mathcal{N}(F) := \int \mathbb{R} e^{-(\eta - i/\varepsilon) P_m(u) F(u) \Phi_N(u)} du$, $\mathcal{D}(F) := \int \int \int \int e^{-(\eta - i/\varepsilon) S N F_m(u) F(u) \Phi_N(u)} du dv \int \int \int \int e^{-(\eta - i/\varepsilon) S N} du dv$. Now $-\log R_j(u) = 12 \log(1 + 2\beta_j(u)\lambda_j) \leq \beta_j(u)\lambda_j \leq \frac{1}{2} A_j \lambda_j$.

$R_j(u) = \frac{1}{2} \log |\left(1 + \frac{\beta_j(u)}{\lambda_j}\right)|$. Hence $\sum_j |\log R_j(u)| < \infty$, so $\Phi_N(u) \rightarrow \Phi^\infty(u) \in (0, 1] \setminus \Phi_N(u) \cup \Phi_\infty(u)$. By coercivity of $P_m P_m$ and $|\Phi_N| \leq 1 / \Phi_N$, we have $\int e^{-\eta P_m(u)} du < \infty$. Thus dominated convergence gives $\mathcal{N}N(F) \rightarrow \mathcal{N}^\infty(F) \setminus \mathcal{N}_N(F) \cup \mathcal{N}_\infty(F)$. Assuming $D_\infty \neq 0$, ratios converge.

For the rate, write $\Phi N' = \Phi N \Psi N, N' \Phi_{\{N'\}} = \Phi_{\{N\}} \Psi_{\{N, N'\}}$,
 $\Psi N, N' := \prod j=N+1^N R_j \Psi_{\{N, N'\}} := \prod j=N+1^N \{N'\} R_j$. Because
 $0 < R_j \leq 10 < R_j \leq 1$, $1 - \Psi N, N' \leq \sum j=N+1^N (1 - R_j) \cdot 1 - \Psi_{\{N, N'\}} \leq \sum j=N+1^N \{N'\} (1 - R_j)$. Set $t_j = 2\beta_j / j$, $j \geq 0$, $t_j = 2\beta_j / j \geq 0$. Since $1 - (1+t) - 1/2 \leq t - (1+t)^{-1/2} \leq t$ for $t \geq 0$, $1 - R_j(u) \leq 2\beta_j(u) / j \leq 2/u / 2A_j \lambda_j \cdot 1 - R_j(u) \leq \frac{2\beta_j(u)}{\lambda_j} \frac{1}{\lambda_j}$. Therefore $|\Phi N'(u) - \Phi N(u)| \leq 2/u / 2 \sum j=N+1^N A_j \lambda_j \cdot |\Phi_{\{N'\}}(u) - \Phi_{\{N\}}(u)| \leq 2/u / 2 \sum j=N+1^N \frac{A_j}{\lambda_j}$. Insert this bound in \mathcal{N}, \mathcal{D} differences and use $|e^{-(\eta-i/\varepsilon)Pm}| \leq e^{-\eta Pm} |e^{-(\eta-i/\varepsilon)P_m}| \leq e^{-(\eta-i/\varepsilon)P_m}$. Then for $C1 := 2|e^{-\eta Pm}| / u / 2du < \infty$, $C_1 := 2 \int e^{-(\eta-i/\varepsilon)P_m} |u| / 2du < \infty$. $|\mathcal{N}N'(F) - \mathcal{N}N(F)| \leq \|F\| / \infty C_1 \sum j=N+1^N A_j \lambda_j \cdot |\mathcal{N}_{\{N'\}}(F) - \mathcal{N}_N(F)| \leq \|F\| / \infty C_1 \sum j=N+1^N \frac{A_j}{\lambda_j} \cdot |\mathcal{D}N' - \mathcal{D}N| \leq C1 \sum j=N+1^N A_j \lambda_j \cdot |\mathcal{D}N| \leq C_1 \sum j=N+1^N \frac{A_j}{\lambda_j}$. For large N , $|\mathcal{D}N| \geq d^* > 0$, $|\mathcal{D}N| \geq d^* > 0$, and $|a'b' - ab| \leq |a-a'||b'| + |a||b'-b||b| \leq \frac{|a'|}{|b'|} |b'| + \frac{|a|}{|b|} |b| \leq \frac{|a'|}{|b'|} + \frac{|a|}{|b|} \leq \frac{|a'|}{|b'|} + \frac{|a|}{|b|}$ gives the stated rate. \square

Theorem 16 (Non-factorized quartic-tail large-NN extension). Let $SN(u,v) = Pm(u) + \sum_{j=m+1}^N ((\lambda j^2 + \beta_j(u)) v_j^2 + \gamma_j v_j^4), S_N(u,v) = P_m(u) + \sum_{j=m+1}^N$
 $\Big(\frac{\lambda_j}{2} v_j^2 + \beta_j(u) v_j^4 + \gamma_j v_j^4 \Big)$, with $\lambda_j \geq \lambda - \epsilon > 0, \beta_j \geq \eta - \epsilon > 0, \gamma_j \geq \gamma - \epsilon > 0$, coercive PmP_m , and $\beta_j(u) \leq A_j \leq u^2, A_j \geq 0$. For $I_j(b) := \int \Re e^{-c((\lambda j^2 + b)t^2 + \gamma_j t^4)} dt, c = \eta - i/\epsilon, b \geq 0, I_j(b) := \int e^{-c((\lambda j^2 + b)t^2 + \gamma_j t^4)} dt$, assume $c = \eta - i/\epsilon, b \geq 0$.

1. $I_j(b) \neq I_{-j}(b) \neq 0$ for all $j, b \geq 0$, $b \neq 0$,
 2. $\sup_{b \geq 0} |\partial_b \log I_j(b)| \leq L_j \sup_{b \geq 0} \{b\}^{\alpha}$, $\|\partial_b \log I_{-j}(b)\| \leq L_{-j}$ and
 $\sum_{j=m+1}^{\infty} L_j A_j < \infty$. $\sum_{j=m+1}^{\infty} \inf_{b \geq 0} I_j(b) < \infty$.

Then for bounded cylinder observables FmF_m ,
 $\omega_{\varepsilon,\eta,N}(Fm) := \int e^{-cSN} Fm(u) du dv / \int e^{-cSN} du dv$ converges as $N \rightarrow \infty$. It satisfies the tail estimate $|\omega_{\varepsilon,\eta,N}(Fm) - \omega_{\varepsilon,\eta,N}(Fm)| \leq C Fm, \varepsilon, \eta \sum_{j=N+1}^{N'} L_j A_j$. The limit $\lim_{N \rightarrow \infty} \omega_{\varepsilon,\eta,N}(Fm)$ is finite if the denominator is nonzero, and satisfies the tail estimate $|\omega_{\varepsilon,\eta,N'}(Fm) - \omega_{\varepsilon,\eta,N}(Fm)| \leq C Fm, \varepsilon, \eta \sum_{j=N+1}^{N'} L_j A_j$.

Proof. Integrate each $v_j v_{-j}$:

$\omega_{\varepsilon, \eta, N}(F_m) = \int_{\mathbb{R}} m e^{-cPm(u)} F_m(u) \Phi N(u) du$, $\int_{\mathbb{R}} m e^{-cPm(u)} \Phi N(u) du, \Phi N(u) = \prod_{j=m+1}^N I_j(\beta_j(u)) I_j(0)$.
 $\omega_{\varepsilon, \eta, N}(F_m) = \frac{\int_{\mathbb{R}} \{m e^{-cPm(u)} F_m(u)\} \Phi N(u) du}{\int_{\mathbb{R}} \{m e^{-cPm(u)}\} \Phi N(u) du}$, \quad
 $\Phi_N(u) = \prod_{j=m+1}^N \frac{I_j(\beta_j(u))}{I_j(0)}$. For each j , $|$
 $|\log I_j(\beta_j(u))| = |\int_0^u \beta_j(b) db| \leq L_j A_j / u \leq 2 \cdot \left| \log \frac{I_j(\beta_j(u))}{I_j(0)} \right| = \left| \int_0^u \beta_j(b) \partial_b \log I_j(b) db \right| \leq L_j A_j |u|$

\wedge^2 . Hence $\sum_{j=m+1}^{\infty} |\log I_j(\beta_j(u))| I_j(0) | \leq \|u\|/2 \sum_{j=m+1}^{\infty} L_j A_j < \infty$, $\sum_{j=m+1}^{\infty} L_j A_j < \infty$, so $\Phi N(u) \rightarrow \Phi \infty(u) \Phi_N(u) / \Phi \infty(u)$ pointwise and $|\Phi N(u)| \leq \exp(B\|u\|/2)$, $B := \sum_{j=m+1}^{\infty} L_j A_j \cdot \|\Phi_N(u)\| \leq \exp(B\|u\|^2)$, $\Phi N(u) = \sum_{j=m+1}^{\infty} L_j A_j$. Thus $|e^{-cP_m(u)} \Phi N(u) F_m(u)| \leq \|F_m\| \infty e^{-\eta P_m(u)} e^{B\|u\|/2} \leq e^{-cP_m(u)} \|\Phi_N(u) F_m(u)\| \leq \|F_m\| \infty e^{-\eta P_m(u)} e^{B\|u\|^2}$, integrable by quartic coercivity; dominated convergence yields numerator/denominator limits and ratio convergence.

For the rate, define $\Delta N, N'(u) := \sum_{j=N+1}^N \log I_j(\beta_j(u)) I_j(0), |\Delta N, N'(u)| \leq \|u\| / 2 \sum_{j=N+1}^N N' L_j A_j$. $\Delta_{N,N'}(u) := \sum_{j=N+1}^N \{N'\} \log \frac{I_j(\beta_j(u))}{I_j(0)}$, where $|\Delta_{N,N'}(u)| \leq \|u\|^2 \sum_{j=N+1}^N \{N'\} L_j A_j$. With $\Phi' = \Phi N e \Delta N, N' \Phi'_N = \Phi_N e^{\Delta_{N,N'}} : |\Phi' - \Phi| \leq |\Phi| \|e \Delta N, N' - 1\| \leq \|B\| \|u\| / 2 \Delta N, N' \|e \Delta N, N'\| \|\Phi'_N - \Phi_N\| \|e \Phi_N\|, e^{\Delta_{N,N'}} - 1 \leq e^{\|B\| \|u\|^2} \|\Delta_{N,N'}\| e^{\|\Delta_{N,N'}\|}$. This gives $|\Phi' - \Phi| \leq e(B + B \tilde{B}) \|u\| / 2 \sum_{j=N+1}^N N' L_j A_j \|\Phi'_N - \Phi_N\| \|e \Phi_N\| \leq e^{\|(B + \tilde{B})\| \|u\|^2} \|u\|^2 \sum_{j=N+1}^N \{N'\} L_j A_j$, for a finite $B \tilde{B}$ (tail-sum bound). Integrating against $e^{-\eta P_m} m^{-\lambda} \eta^{-m}$ gives numerator/denominator Cauchy bounds, and the ratio estimate follows as in Theorem 15. \square

Corollary 17 (Intrinsic sufficient conditions for Theorem 16). For each j , define block moments $M^j(1) := \sup_{b \geq 0} \mathbb{E} v_j b[S_j, b]$, $M^j(2) := \sup_{b \geq 0} \mathbb{E} v_j b[t_2]$, $\overline{M}^j(1) := \sup_{b \geq 0} \mathbb{E} v_j b[S_j, b]$, $\overline{M}^j(2) := \sup_{b \geq 0} \mathbb{E} v_j b[t_2]$, where $v_j b(dt) := e^{-\eta S_j} b(t) [e^{-\eta S_j} b(dt)]$, $\nu_j(dt) := \frac{e^{-\eta S_j}}{\int e^{-\eta S_j} dt}$, $S_j(t) = \left(\frac{\lambda_j}{2} + b \right) t^2 + \gamma_j t^4$. If $\varepsilon > \sup_j M^j(1)$, and $\sum_j j \overline{M}^j(1) < \infty$, and $\sum_j j \overline{M}^j(2) < \infty$, then hypotheses (Q1)–(Q2) in Theorem 16 hold with $L_j = |c| M^j(2) / M^j(1) \varepsilon$, $L_{-j} = |c| \overline{M}^j(2) / \overline{M}^j(1) \varepsilon$.

Proof. By Theorem 19 applied to each block $S_j, bS_{\{j,b\}}$: $|I_j(b)| \geq (\int e^{-\eta S_j} b)$ $(1 - M^- j(1)\varepsilon) > 0$, $|I_j(b)| \geq \left(\int e^{-\eta S_{\{j,b\}}} dt\right) \left(1 - \frac{\overline{M}^{\{1\}}_j}{\varepsilon}\right) > 0$, so (Q1) holds. Also $\partial b I_j(b) = -c \int t^2 e^{-c S_j} b(t) dt$, $\partial b I_j(b) = -c \int t^2 e^{-c S_{\{j,b\}}(t)} dt$, thus $|\partial b \log I_j(b)| \leq |c| \int t^2 e^{-\eta S_j} b dt |e^{-\eta S_j} b dt (1 - M^- j(1)/\varepsilon) \leq |c| M^- j(2) (1 - M^- j(1)/\varepsilon) |\partial b \log I_j(b)| \leq \frac{|c| \int t^2 e^{-\eta S_{\{j,b\}}} dt}{\int e^{-\eta S_{\{j,b\}}} dt} \frac{\int e^{-\eta S_{\{j,b\}}} dt}{(1 - \overline{M}^{\{1\}}_j/\varepsilon)} \leq \frac{|c|}{\overline{M}^{\{2\}}_j} \frac{1}{1 - \overline{M}^{\{1\}}_j/\varepsilon}$. This is (Q2). Summability is exactly the second assumption. \square

Theorem 18 (Non-factorized quadratic-mixing large-NN extension). Let $SN(u, v) = Pm(u) + 12v^\top(DN(u) + KN)v$, $S_N(u, v) = P_m(u) + \frac{1}{2}|v|$.
 $\|big(D_N(u) + K_N\|big)v$, where $u \in \mathbb{R}^m$, $v \in \mathbb{R}^{N-m}$, $D_N(u) = diag(dm+1(u), \dots, dN(u))$, $D_N(u) = diag(d_{m+1}(u), \dots, d_{N-m}(u))$ with $d_j(u) = \lambda j + 2\beta j(u)$, $\beta j(u) = \sum_{i=1}^{m+1} a_{ij} u_i$, $a_{ij} \geq 0$, $\lambda j \geq \lambda - > 0$. $d_j(u) = \lambda da_j + 2\beta_j(u)$, $\beta_j(u) = \sum_{i=1}^{m+1} a_{ij} u_i^2$, $a_{ij} \geq 0$, $\lambda da_j \geq \lambda - > 0$. Assume coercive PmP_m and $A_j := \sum_{i=1}^{m+1} a_{ij}$, $\sum_{j=m+2}^N A_j := \sum_{i=1}^{m+1} a_{ij}$, $\lambda A_j := \sum_{i=1}^{m+1} a_{ij}$. Let $K = (kjk)_{j,k > m}$, $K = (\kappa_{jk})_{j,k > m}$ be real symmetric, KNK_N its principal truncation, and with $\Lambda = diag(\lambda_j)$, $\Lambda = diag(\lambda_j)$ define $\tilde{K} := \Lambda - 1/2\Lambda^{-1/2}$, $\tilde{K} := \Lambda^{-1/2}K\Lambda^{-1/2}$. Assume $\|\tilde{K}\| < \theta < 1$, $\|\tilde{K}\| < 1 < \theta$, $\|\tilde{K}\| < \theta < 1$.

$\|\tilde{K}\|_1 < \infty$, and $\tau N := \|K \circ P_N K \circ P_N\| / \int_0^{\tau N} \det(DN) dt = \|\tilde{K}\|_1$. $P_N \tilde{K} P_N \tilde{K} P_N \tilde{K} P_N \tilde{K}$ to 0 ($P_N \tilde{K} P_N$: projection onto indices $m+1, \dots, Nm+1, \dots, N$).

Then for bounded cylinder F_m ,

$\omega_{\varepsilon, \eta, N}(F_m) = \int e^{-cS} F_m(u) du dv \int e^{-cS} du dv, c = \eta - i/\varepsilon, \eta > 0, \omega_{\varepsilon, \eta} \sim \varepsilon$,
 $\eta \sim N$, $\omega_{\varepsilon, \eta}(F_m) = \frac{1}{2} \int e^{-cS} F_m(u) du dv \int e^{-cS} du dv$,
 $c = \eta - i/\varepsilon$, $\eta > 0$, converges as $N \rightarrow \infty$ to ∞ (if the limiting denominator is nonzero), and there exists $C_{F_m, \varepsilon, \eta} > 0$ such that
 $|\omega_{\varepsilon, \eta, N}(F_m) - \omega_{\varepsilon, \eta, N}(F_m)| \leq C_{F_m, \varepsilon, \eta} (\sum_{j=N+1}^{Nm+1} A_j j + \tau N), N' > N \geq m$,
 $|\omega_{\varepsilon, \eta}(F_m) - \omega_{\varepsilon, \eta}(F_m)| \leq C_{F_m, \varepsilon, \eta} (\sum_{j=N+1}^{Nm+1} A_j j + \tau N)$,
 $N' > N \geq m$.

Proof. Integrate in vv : $\int_{\mathbb{R}} N - me - c/2 v^\top (DN + KN) v dv = CN(c) \det(DN + KN) - 1/2$,
 $\int_{\mathbb{R}} \int_{\mathbb{R}} (N - me - c/2 v^\top (DN + KN) v) dv = C_N(c)$
 $\det(D_N + K_N)^{-1/2}$, with uu -independent $C_N(c)C_{\bar{N}}(c)$ that cancels in normalized ratios. So

$\omega_{\varepsilon, \eta, N}(F_m) = \int_{\mathbb{R}} me - cP_m(u)F_m(u)\Phi N(u) du \int_{\mathbb{R}} me - cP_m(u)\Phi N(u) du, \Phi N(u) := \det(DN(u) + KN) - 1/2$,
 $\omega_{\varepsilon, \eta, N}(F_m) = \frac{1}{2} \int_{\mathbb{R}} \int_{\mathbb{R}} (me - cP_m(u)\Phi N(u)) dv du$,
 $\Phi N(u) := \det(D_N(u) + K_N)^{-1/2}$. Write $\Phi N(u) = \Phi N \text{diag}(u) \Delta N(u)$,
 $\Phi N(u) = \Phi N \text{diag}(u) \Delta N(u)$, $\Phi N \text{diag}(u) := \prod_{j=m+1}^N \Delta_j(u)$,
 $\Delta_j(u) := \det(I + M_j(u))^{-1/2}$,
 $\Delta(u) := \det(I + M_N(u))^{-1/2}$,
 $MN(u) := DN(u) - 1/2 K_N D_N(u) - 1/2 M_N(u) := D_N(u)^{-1/2} K_N D_N(u)^{-1/2}$.

By Theorem 15, $\Phi N \text{diag}(u)$ has Cauchy tail control by
 $\sigma_N := \sum_{j=N+1}^{\infty} A_j / j$.

Since $DN(u) \geq \Lambda D_N(u) \geq \Lambda \Delta N(u)$, we have

$\|MN(u)\| \leq \|K\| < \theta$, $\|MN(u)\| \leq \|K\| = K_1$, $|M_N(u)| \leq \|\tilde{K}\| \leq \theta$,
 $|M_N(u)|_1 \leq \|\tilde{K}\|_1 = K_1$. Thus $I + MN(u)I + M_N(u)$ is invertible and $|\log \det(I + MN(u))| \leq 11 - \theta$,
 $|\log \det(I + M_N(u))| \leq 11 - \theta$, hence $|\Delta N(u)| \leq C \Delta |\Delta N(u)| \leq C \Delta$ uniformly.

Now set $Q(u) := \text{diag}((\lambda_j/d_j(u))/2), 0 < Q(u) \leq I$. Then
 $Q(u)K \circ Q(u)M \circ \text{infy}(u) = Q(u)\tilde{K}(u)$ and
 $MN(u) = PNM(u)PNM_N(u) = P_N M_N \text{infy}(u)P_N$, so $\|M\circ(u) - MN(u)\| \leq \|K\| \leq K_1$,
 $\|M\circ(u) - MN(u)\| \leq \|K\| = K_1$. On $\|A\|, \|B\| \leq \theta < 1$, $|\log \det(I + A) - \log \det(I + B)| \leq \frac{1}{2} \log \frac{1}{1 - \theta} |A - B|$, thus $|\Delta\circ(u) - \Delta N(u)| \leq C \Delta |\Delta N(u)| \leq C \Delta \tau N |\Delta N(u)|$ uniformly in u .

Therefore, for $N' > N$, $\Phi N' - \Phi N = \Delta N'(\Phi N' \text{diag} - \Phi N \text{diag}) + \Phi N \text{diag}(\Delta N' - \Delta N)$,
 $\Phi N' - \Phi N = \Delta N'(\Phi N' \text{diag} - \Phi N \text{diag}) + \Phi N \text{diag}(\Delta N' - \Delta N)$, and
 $|\Phi N'(u) - \Phi N(u)| \leq C_1 \epsilon B / u / 2(\sigma N + \tau N)$,
 $|\Phi N'(u) - \Phi N(u)| \leq C_1 \epsilon B / u / 2(\sigma N + \tau N)$, for constants C_1, B independent of N, u, N, u .
Multiplying by $|e - cP_m(u)| = e - \eta P_m(u) e^{-cP_m(u)}$ gives an integrable envelope by quartic coercivity. Dominated convergence plus the standard ratio-difference estimate yields convergence and the stated mixed tail rate. \square

Partition-Factor Non-Vanishing Bounds

Theorem 19 (Moment criteria). Let $A\eta = \int e - \eta S(x) dx \in (0, \infty)$, $A_\eta = \int e^{\{-\eta S(x)\}} dx \in (0, \infty)$ and $Z_{\varepsilon, \eta} := \int e^{-(\eta - i/\varepsilon)S(x)} dx = A\eta \mathbb{E}_{\mu\eta}[e^{iS/\varepsilon}]$, $\mu\eta(dx) := e^{-\eta S(x)} A\eta dx$. $Z_{\varepsilon, \eta} = \int e^{\{-(\eta - i/\varepsilon)S(x)\}} dx = A_\eta \mathbb{E}_{\mu\eta}[e^{iS/\varepsilon}]$. Define $M_1 := \mathbb{E}_{\mu\eta}[S]$, $M_2 := \mathbb{E}_{\mu\eta}(S^2)$. $M_1 := \mathbb{E}_{\mu\eta}[S]$, $M_2 := \mathbb{E}_{\mu\eta}(S^2)$. Then $|Z_{\varepsilon, \eta}| \geq A\eta(1 - M_1\varepsilon)$, $|Z_{\varepsilon, \eta}| \geq A\eta(1 - M_2\varepsilon^2)$. Hence if $\varepsilon > M_1/varepsilon > M_1$ or $\varepsilon^2 > M_2/2\varepsilon > M_2/2$, then $Z_{\varepsilon, \eta} \neq 0$.

Proof. First bound: $|\mathbb{E}[eiX]| = |1 + \mathbb{E}(eiX - 1)| \geq 1 - \mathbb{E}|eiX - 1|, X = S/\varepsilon$. $\left| \mathbb{E}[e^{iX}] \right| = |1 + \mathbb{E}(e^{iX} - 1)| \geq 1 - \mathbb{E}|e^{iX} - 1|$, $X = S/\varepsilon$. Since $|e^{it} - 1| \leq t|e^{it} - 1| \leq t$, $|\mathbb{E}[e^{iS/\varepsilon}]| \geq 1 - M_1\varepsilon$. $\left| \mathbb{E}[e^{iS/\varepsilon}] \right| \geq 1 - M_1\varepsilon$. Multiply by $A\eta A_\eta$.

Second bound: $\Re \mathbb{E}[e^{iS/\varepsilon}] = \mathbb{E}[\cos(S/\varepsilon)] \geq 1 - 12\mathbb{E}[(S/\varepsilon)^2] = 1 - M_2\varepsilon^2$. $\Re \mathbb{E}[e^{iS/\varepsilon}] = \mathbb{E}[\cos(S/\varepsilon)] \geq 1 - \frac{1}{2}\mathbb{E}[S^2]$. Now $|z| \geq \Re z \geq \Re z$ gives the inequality for $|Z_{\varepsilon, \eta}|$. \square

Observable-Class Extension

Theorem 20 (Continuity on Schwartz and weighted Sobolev classes). Let $\mathcal{I}(F) = \int \mathbb{R} dei\Phi(y) W(y) F(Ay) dy$, $\mathcal{I}(F) = \int \mathbb{R} dei\Phi(y) R^d e^{i\Phi(y)} W(y) F(Ay) dy$, with $A \in GL(d, \mathbb{C})$ in $GL(d, \mathbb{C})$ and $|W(y)| \leq C_0 e^{-c_4 \|y\|^4/4 + c_2 \|y\|^2}$, $c_4 > 0$, $|W(y)| \leq C_0 e^{-c_4 \|y\|^4/4 + c_2 \|y\|^2}$, $c_4 > 0$. Then:

1. for every integer $k > dk > d$, there exists CkC_k such that $|\mathcal{I}(F)| \leq Ck \sup_x (1 + \|x\|)^k |F(x)|$, $F \in \mathcal{S}(\mathbb{R}^d)$, $|\mathcal{I}(F)| \leq C_k \sup_x (1 + \|x\|)^k |F(x)|$, $F \in \mathcal{S}(R^d)$;
2. for every $k > d/2k > d/2$, there exists $Ck'C_k'$ such that $|\mathcal{I}(F)| \leq C_k' (1 + \|x\|/2)^k |F(x)|$, $F \in H^0(k)$, $|\mathcal{I}(F)| \leq C_k' (1 + \|x\|/2)^k |F(x)|$, $F \in H^0(k)$.

Consequently, normalized functionals $\omega(F) = \mathcal{I}(F)/\mathcal{I}(1)$, $\Omega(F) = |\mathcal{I}(F)|/|\mathcal{I}(1)|$ (when $\mathcal{I}(1) \neq 0$) extend continuously from Gaussian-polynomial test families to both classes.

Proof. For Schwartz: $|F(Ay)| \leq CApk(F)(1 + \|y\|)^{-k}$, $p_k(F) := \sup_x (1 + \|x\|)^k |F(x)|$, $|F(Ay)| \leq C_A p_k(F)(1 + \|y\|)^{-k}$, $p_k(F) := \sup_x (1 + \|x\|)^k |F(x)|$. Hence $|\mathcal{I}(F)| \leq C_0 CApk(F) \int e^{-c_4 \|y\|^4/4 + c_2 \|y\|^2} (1 + \|y\|)^{-k} dy$, $|\mathcal{I}(F)| \leq C_0 C_A p_k(F) \int e^{-c_4 \|y\|^4/4 + c_2 \|y\|^2} (1 + \|y\|)^{-k} dy$, and the integral is finite.

For weighted Sobolev: $|\mathcal{J}(F)| \leq \|W(\cdot)(1+|\cdot|^2)^{-k/2}\|_{L^2} \|(1+|y|^2)^{k/2} F(Ay)\|_{L^2}$.
 $\|\mathcal{I}(F)\| \leq \|W(\cdot)(1+|\cdot|^2)^{-k/2}\|_{L^2} \|(1+|y|^2)^{k/2} F(Ay)\|_{L^2}$. The first factor is finite by quartic decay; the second is bounded by $C A^k \|F\|_{H^0, kC_A^{-1}|F|_{H^0, 0, k}}$ after linear change of variables. \square

Schwinger-Dyson and τ_μ Scale Covariance

Definition 21 (cc-invariant quantity). For parameter triples $(\kappa, \eta, h) (\backslash kappa, \backslash eta, h)$, define $c := (\eta - i/h)\kappa$. $c := (\backslash eta - i/h)\backslash kappa$. A quantity is called cc-invariant if it is unchanged under any parameter change that leaves cc fixed (equivalently, unchanged along $\tau\mu\backslash tau_mu$ -orbits).

Theorem 22 (Finite-dimensional Schwinger-Dyson identity). Let $c = \eta - i/\epsilon c = \eta \epsilon a - i/\epsilon \eta \epsilon$ and $\mathcal{I}_c(F) := \int e^{-cS(x)} F(x) dx$. Then $\mathcal{I}_c(F) = \int e^{\eta \epsilon a - i/\epsilon \eta \epsilon} \{ -cS(x) \} F(x) dx$. Assume integrability and vanishing boundary flux for admissible V and vector field S . Then $\mathcal{I}_c(V \cdot \nabla S) = \mathcal{I}_c \mathcal{I}_c(\nabla \cdot (VF))$. $\mathcal{I}_c(V \cdot \nabla S) = \frac{1}{c} \mathcal{I}_c(\nabla \cdot V) + \frac{1}{c} \mathcal{I}_c(S \cdot \nabla V)$. If $\mathcal{I}_c(1) \neq 0$, then $\omega_c(V \cdot \nabla S) = \mathcal{I}_c \omega_c(\nabla \cdot (VF))$. $\omega_c(V \cdot \nabla S) = \frac{1}{c} \mathcal{I}_c(\nabla \cdot V) + \frac{1}{c} \mathcal{I}_c(S \cdot \nabla V)$. In particular, for constant $V = eiV = e_i$ and $F \equiv IF$ we have $\omega_c(\partial_i S) = 0$. $\omega_c(\partial_i S) = 0$.

Proof. $0 = \int \nabla \cdot (e - cS) \nabla F dx = \int e - cS (\nabla \cdot VF - cV \cdot \nabla SF) dx$. $0 = \int e - cS (\nabla \cdot VF - cV \cdot \nabla SF) dx = \int e - cS (\nabla \cdot VF - cV \cdot \nabla S + cV \cdot \nabla F) dx$. Rearrange, then divide by $c(1)$ for the normalized form. \square

Theorem 23 (Exact $\tau\mu\backslash\tau\mu$ covariance). For $\omega\kappa,\eta,h(F):=\int e^{-(\eta-i/h)\kappa S(x)}F(x)dx\int e^{-(\eta-i/h)\kappa S(x)}dx$, $\omega_{\kappa,\eta,h}(F):=\frac{1}{2}\int e^{-(\eta-i/h)\kappa S(x)}F(x)dx\int e^{-(\eta-i/h)\kappa S(x)}dx$, define $\tau\mu:(\kappa,\eta,h)\mapsto(\mu\kappa,\eta/\mu,\mu h)$, $\mu>0$. $\tau\mu\backslash\mu:(\kappa,\eta,h)\mapsto(\mu\kappa,\eta/\mu,\mu h)$, $\mu>0$. Then $\omega\kappa,\eta,h(F)=\omega\tau\mu(\kappa,\eta,h)(F)$. $\omega_{\kappa,\eta,h}(F)=\omega_{\tau\mu\backslash\mu}(\kappa,\eta,h)(F)$.

Proof. Directly, $(\eta\mu - i\mu h)(\mu\kappa) = (\eta - i/h)\kappa \cdot \left(\frac{\eta}{\mu} - \frac{i}{\mu h}\right)$. Hence numerator and denominator kernels are unchanged. \square

Proposition 24 (Kernel-parameter unification of $\tau\mu\backslash\tau\mu$ and Schwinger-Dyson).
Set $c := (\eta - i/h)\kappa$. Then:

1. $\tau\mu\backslash\tau\mu$ preserves cc ,
 2. the *Schwinger-Dyson identity* in Theorem 22 depends only on cc .

Hence two parameter triples on the same $\tau\backslash\tau\mu$ -orbit define identical Schwinger-Dyson relations for all admissible observables.

Proof. Part (i) is exactly the computation in Theorem 23. For part (ii), Theorem 22 is written purely in terms of $\mathcal{I}c(\cdot)\backslash\mathit{mathcal{I}}_c(\cdot)$, hence only through cc . Therefore $\tau\mu\backslash\tau\mu$ -related parameter triples yield the same SD equations. \square

Dependency Chain

The proofs in this manuscript now close in the following order:

1. Sections 2–5: core scoped Claim 1 closure.
2. Theorems 15, 18, 16, and Corollary 17: large-NN coupled extensions (Gaussian-tail rate, non-factorized quadratic-mixing determinant class, non-factorized quartic-tail class, and intrinsic moment-based sufficient conditions).
3. Theorem 19: explicit non-vanishing criteria for partition factors.
4. Theorem 20: observable-class extension to Schwartz/Sobolev.
5. Theorems 22, 23, and Proposition 24: Schwinger-Dyson identities, exact scale-flow covariance, and their shared invariant kernel parameter.

Conclusion

This manuscript now gives a theorem-grade chain from the static/finite-dimensional variational-delta picture to a broad scoped family of oscillatory states including:

1. exact projective closure and de-regularization,
2. explicit semiclassical channel expansion,
3. large-NN mode-coupled convergence with quantitative tail control (Gaussian-tail, non-factorized quadratic-mixing, and non-factorized quartic-tail classes), with intrinsic moment criteria for quartic-tail hypotheses,
4. non-vanishing control for normalization factors,
5. extension to large observable classes,
6. Schwinger-Dyson identities and scale-flow covariance with a shared cc-invariance structure.

Open frontier (outside this closure): full interacting, non-factorized, genuinely field-theoretic continuum limits with uniform renormalization control beyond the scoped polynomial block-tail class.
